**Keep fixed linear  
effect model  
using LASSO  
instead of  
least squares**

# Fixed Linear Effect Model

- ▶ Back to

$$y_i = \beta_0 + \sum_{j=1}^p \beta_j x_{ij} + \epsilon_i$$

- ▶ All  $\beta_0, \beta_1, \dots, \beta_p$  into vector  $\beta$  of length  $(p + 1)$

$$y = X\beta + \epsilon$$

- ▶ Only random componente:  $\epsilon$  with

$$E(\epsilon) = 0 \text{ and } \text{var}(\epsilon) = I * \sigma^2$$

# Parameter Estimation

- ▶ Least Squares

$$\hat{\beta}_{LS} = \operatorname{argmin}_{\beta} ||y - X\beta||^2$$

- ▶ Normal Equations

$$(X^T X) \hat{\beta}_{LS} = X^T y$$

- ▶ Existence of  $(X^T X)^{-1}$ ?

1. Yes:  $\hat{\beta}_{LS} = (X^T X)^{-1} X^T y$
2. No:  $b_0 = (X^T X)^{-} X^T y$

with  $(X^T X)^{-}$  being a generalized inverse of  $(X^T X)$

# Generalized Inverse

- ▶ System of equations

$$Ax = y$$

with coefficient matrix  $A$ , vector of unknowns  $x$  and vector of right hand side  $y$

- ▶ If  $A^{-1}$  exists, then unknowns  $x = A^{-1}y$
- ▶ If  $A^{-1}$  does not exist,  $x = A^{-}y$  is one solution with  $A^{-}$  being a generalized inverse
- ▶ Generalized inverse  $A^{-}$  defined by

$$AA^{-}A = A$$

# Solutions

- ▶ Why is  $A^-$  a solution
  - ▶ if  $AA^-A = A$ , then  $AA^-Ax = Ax$
  - ▶ when  $Ax = y$ , this gives  $A(A^-y) = y$
  - ▶ hence  $A^-y = x$  is a solution
- ▶ If  $A^-$  is a generalized inverse of  $A$  then  $Ax = y$  has solutions

$$\tilde{x} = A^-y + (A^-A - I)z$$

for arbitrary  $z$

- ▶ Proof

$$A\tilde{x} = AA^-y + A(A^-A - I)z = AA^-y + (AA^-A - AI)z = AA^-y = y$$

because  $AA^-A = A$ .

# Results

- ▶  $b_0 = (X^T X)^- X^T y$  is a solution to  $(X^T X)b_0 = X^T y$
- ▶ But  $b_0$  is not unique, because for any  $(X^T X)^-$

$$\tilde{b}_0 = (X^T X)^- X^T y + ((X^T X)^- (X^T X) - I)z$$

is also a solution

- ▶  $b_0$  cannot be an estimate for  $\beta$

# Estimable Functions

Idea: construct linear functions ( $q^T \beta$ ) of the parameters  $\beta$  such that

- ▶ estimator can be found from  $b_0$
- ▶ independent of choice of  $b_0$

Such linear functions  $q^T \beta$  must satisfy

$$q^T \beta = t^T E(y)$$

for any vector  $t$ , then  $q^T \beta$  is **estimable**

- ▶ Determine  $q$  as

$$q^T = t^T X$$

## Invariance to $b_0$

When  $q^T \beta$  is estimable, then

- ▶  $q^T b_0$  is always the same, independent of choice of  $b_0$
- ▶ Why?
- ▶ With  $q^T = t^T X$

$$q^T b_0 = t^T X b_0 = t^T X (X^T X)^- X^T y$$

is independent of choice of  $b_0$  because  $X(X^T X)^- X^T$  is independent of choice of  $(X^T X)^-$

# Summary

Use of generalized inverse  $(X^T X)^-$  of normal equations yields

- ▶ solutions  $b_0$
- ▶ estimable functions  $q^T b_0$  which estimate  $q^T \beta$
- ▶ independent of  $b_0$

But for genomic data

- ▶ no possibility to determine important SNP loci
- ▶ need an alternative to least squares

# Alternatives To Least Squares

Desirable properties

1. **Subset Selection:** determine important predictors
2. **Shrinkage:** limit parameter estimates to certain area
3. **Dimension Reduction:** Reduce  $p$  predictors to  $m$  linear combinations where  $m < p$

# LASSO

- ▶ ... stands for Least Absolute Shrinkage and Selection Operator
- ▶ ... combines subset selection (1) and shrinkage (2)
- ▶ shrinkage is achieved by introduction of penalty term
- ▶ subset selection is due to the form of penalty term

# Shrinkage

similar to Least Squares

Lambda  
estimated  
from data

- penalty term added to least squares criterion

$$\hat{\beta}_{LASSO} = \underset{\beta}{\operatorname{argmin}} \left\{ \sum_{i=1}^n \left( y_i - \beta_0 - \sum_{j=1}^p \beta_j x_{ij} \right)^2 + \lambda \sum_{j=1}^p |\beta_j| \right\}$$

- large values of  $|\beta_j|$  are penalized compared to small  $|\beta_j|$

Minimization

**LASSO penalty term:**  
> grows with the number of  
elements in beta greater than 0

# Subset Selection

valid  
parameter  
estimates

Parameter estimate  
using least squares  
in the perfect world

Find  $\lambda$

**Lambda determines how much penalty  
is imposed on the estimates  
> large lambda impose high penalty**

- ▶  $\lambda$  is an additional parameter to be estimated from data
- ▶ use cross validation
  - ▶ split data randomly into training set (80 – 90%) and test set (10 – 20%)
  - ▶ assume a certain  $\lambda$  value and do parameter estimation with training data
  - ▶ try to predict test data with estimated parameters
  - ▶ repeat this many times
  - ▶ take that  $\lambda$  with the best predictive performance

**Cross validation:**

- divide dataset into two parts (training and test)
- assume a certain lambda
- estimate parameters in training data
- predict observations in test and see prediction accuracy
